ABSTRACT

Dinitrogen activation plays an important role in the production of many essential nitrogen based compounds needed for all life. Using density functional theory together with dispersion correction (DFT+D), the activation of molecular nitrogen with a gas phase Zr dimer and a Zr dimer loaded C₆₀ is investigated. The present calculations show that the optimised *trans*-Zr₂N₂ configuration is planar but this configuration exhibits a butterfly shape when it is supported by C₆₀. Furthermore, it is shown that the activation of dinitrogen is facilitated by the Zr dimer stabilized by C₆₀. Additional calculations are carried out to look at the products of the reactions with H₂ and a catalytic cycle for the reduction of N₂ to NH₃ is constructed. Reaction of two molecules of H₂ with Zr₂N₂ molecule loaded C₆₀ is exothermic while reaction of only one molecule of H₂ with free Zr₂N₂ molecule is exothermic again highlighting the importance of stabilization with C₆₀.

I. INTRODUCTION

Molecular nitrogen (N₂) is the most abundant component of the atmosphere on Earth and is an essential element in the chemistry of life. Due to its high bond strength (N≡N triple bond length = 109.768 pm and dissociation energy D₀ = 941.7 kJ mol⁻¹),¹ it is very difficult to oxidize or reduce. Though the inertness of dinitrogen is useful in chemical reactions in the absence of air and water, a wide variety of reactions are also considered to dissociate strong N₂ triple bond for the formation of useful products.

Dinitrogen activation is an important process in the cleavage of the N₂ triple bond. This process is fundamentally important for the synthesis of nitrogen-containing molecules essential for all life. The Haber process² is the principal industrial process for N₂ activation. In this successful commercial process, N₂ reacts with three equivalents of H₂ gas over a metal catalyst to yield ammonia. It is a large scale process with high energy demands and associated transport costs. Dinitrogen has also been activated by a class of enzymes called nitrogenases in biological systems,^{3–5} soluble metal complexes^{6–9} and bare transitional dimers in matrix isolation experiments.^{10–12}

Matrix (chemically inert substance) isolation technique, a powerful experimental tool to study the reactive species and their intermediates, has been used to activate dinitrogen by reacting bare transition metal atoms and dimers giving important insight into the bonding properties and mechanisms.^{10–12} For example, matrix isolation experiments were used to synthesize and characterize the Ti dimer at low temperature using noble gas as matrix.¹⁰ Complete cleavage of the strong N≡N strong triple bond by the reaction of Ti₂ with N₂ in a single step in noble gas matrix was reported by Hans-Jörg Himmel *et al.*^{13,14} The successful cleavage of N₂ molecule with Ti₂ dimer in noble gas matrices led to enormous interest in developing new catalytically active materials that can stabilize metal atoms or dimers for dinitrogen activation.

The buckyball structured carbon fullerenes (C₆₀) are promising candidate materials for developing catalytically active materials as they have outer surface structures with very high mechanical stability at higher pressures and temperatures.^{15,16} Considerable research effort has been carried out on the catalytic activity of metal or metal clusters absorbed C₆₀ system.^{17–21} For example, titanium decorated C₆₀ was considered as an efficient storage media for hydrogen because of the weak bonding nature between pure C₆₀ and hydrogen.²² In a previous study,²³ we proposed the possibility of

Ti₂ loaded C₆₀ as a promising stable system for splitting dinitrogen molecule.

Experimental reaction between laser-ablated Zr and N₂ has been reported and the resultant structure exhibits a four-membered cyclic Zr₂(μ-N₂) species with D_{2h} symmetry as observed for Ti₂N₂.²⁴ However, there is no report on the stabilisation of Zr dimer with C₆₀ and its reactivity with N₂. In the present study, plane wave based density functional theory with dispersion correction (DFT+D) is applied to examine the reactivities of gas phase Zr dimer and Zr dimer chemisorbed on C₆₀ with molecular nitrogen. Additional calculations were carried out to examine the products of the reactions with H₂ leading to the formation of NH₃. Structural details, reaction energies, a catalytic cycle for reduction of N₂ to NH₃ with Zr₂C₆₀ as catalyst and relative energies of the intermediates formed during the reaction N₂ + 3H₂ → 2NH₃ are reported. Furthermore, the hydrogenated products of the *free* Zr₂N₂ molecule and their reaction energies are compared to that of Zr₂N₂C₆₀.

II. COMPUTATIONAL METHODS

The calculations are based on density functional theory. The VASP code,^{25,26} which performs this calculation solving the standard Kohn-Sham (KS) equations, was used. The exchange and correlation term was modelled using the generalized gradient approximation (GGA) parameterized by Perdew, Burke, and Ernzerhof (PBE).²⁷ In all cases we have used a plane-wave basis set with a cut off value of 500 eV. Structural optimizations were performed in all calculations using conjugate a gradient algorithm²⁸ until the residual forces were always smaller than 0.001 eV/Å. A single k-point (Γ) point was used in all calculations to represent the Brillouin zone due to the large super cell. Cubic supercells with 25 Å were used in all calculations to ensure that the two adjacent structures do not interact with each other. The same supercell was used to calculate the energies of N₂, H₂ and NH₃ molecules. Reaction energies were calculated using the following equation (1)

$$E_r = E(M-C_{60}) - E(C_{60}) - E(M) \quad (1)$$

where $E(C_{60})$ is the total energy of a pristine C₆₀ molecule, $E(M-C_{60})$ is the total energy of a molecule interacting C₆₀ and $E(M)$ is the total energy of an isolated molecule.

Here, van der Waals (vdW) interactions were included by using the pair-wise force field as implemented by Grimme *et al.*²⁹ in the VASP package. The efficacy of the pseudopotentials and basis sets for C were tested and reported in our recent theoretical work.³⁰ The calculated bond distances of gas phase N₂ and H₂ were 1.12 Å and 0.75 Å respectively. These values agree well with the corresponding experimental values of 1.10 Å³¹ and 0.74 Å³² indicating that the efficacy of the pseudopotentials and basis sets used for N and H.

III. RESULTS AND DISCUSSIONS

A. The formation of *cis*- and *trans*-Zr₂N₂ complexes from gas phase Zr₂ and N₂

Molecular structures of Zr₂N₂ in the form of *cis* and *trans* configurations were first optimised. Figure 1 shows the resultant

FIG. 1. DFT optimised structures of *cis*- and *trans*-Zr₂N₂ together with structural parameters and Bader charges on Zr and N atoms.

DFT optimised structures together with the bond distances and Bader charges. In the *cis* configuration, N₂ laterally interacts with Zr dimer forming a cyclic structure. A bond elongation of 0.13 Å in the N₂ molecule is observed compared to the value calculated for gas phase N₂. The Zr-Zr bond distance also increases by 0.46 Å compared to its gas phase Zr dimer. This clearly indicates that N₂ molecule is activated by Zr dimer but the degree of activation did not lead to the cleavage of N₂ molecule. The Bader charge analysis shows there is a charge transfer (1.36 |e|) from the Zr dimer to the N₂ molecule forming strong bonds between Zr and N. The reaction energy for the formation of *cis*-Zr₂N₂ from N₂ and Zr₂ is -143.8 kJmol⁻¹ suggesting that this process is thermodynamically favourable.

The optimised structure of *trans*-Zr₂N₂ [Zr(μ-N)₂Zr] is planar and cyclic with alternating Zr and N atoms as observed for the Ti₂N₂ in the experiment¹⁰ and previous theoretical DFT calculations.²³ In the optimised structure the Zr-N bond length is ~1.95 Å which is 0.15 Å and 0.20 Å longer than the calculated and experimental Ti-N bond length values, respectively. The N-Zr-N and Zr-N-Zr bond angle values are ~88.5° and ~91.0° respectively. These values are closer to the corresponding values calculated for *trans*-Ti₂N₂ (87.3° and 92.7°). The longer distances indicate that Zr-N bond strength is weaker than that of Ti-N. This is because of the larger atomic radius of Zr than that of Ti.

The Zr-Zr and N-N separations are 2.79 Å and 2.72 Å respectively in our present calculations. The N-N separation clearly indicates that there is no direct interaction between the two N atoms. The formation of a Zr₂N₂ molecule from Zr₂ and N₂ is associated with an energy change of -440 kJ mol⁻¹. This indicates that the *trans*-Zr₂N₂ structure is thermodynamically stable compared to its starting structures (N₂ and Zr₂). Furthermore, the *trans* complex is 296.2 kJmol⁻¹ more stable than the *cis*-complex. The Bader charge analysis³³ shows that Zr is oxidized and N is reduced by equal quantities retaining the net charge of the molecule zero.

Spectroscopic and theoretical studies of dinuclear zirconium complexes show that Zr₂N₂ core can be planar or bent based on the metal center or steric effect or *cis/trans* configuration.³⁴ However, there is no report available in the literature on the gas phase structures of *cis* and *trans*-Zr₂N₂.

B. The formation of Zr_2C_{60} , *cis*- $\text{Zr}_2\text{N}_2\text{C}_{60}$ and *trans*- $\text{Zr}_2\text{N}_2\text{C}_{60}$ complexes

In this section we discuss the structures, Bader charges and reaction energies of *cis*- $\text{Zr}_2\text{N}_2\text{C}_{60}$ and *trans*- $\text{Zr}_2\text{N}_2\text{C}_{60}$ complexes formed between the Zr_2C_{60} and N_2 . The structure of a Zr dimer chemisorbed onto C_{60} (Zr_2C_{60}) was first calculated. Reaction energy for the formation of Zr_2C_{60} from a C_{60} and a Zr dimer is calculated to be -223 kJ mol^{-1} . In the optimised structure, the Zr-Zr distance is 2.80 \AA , which is longer than the free Zr dimer bond length of 2.01 \AA . This indicates that the dimer must have a substantial interaction with C_{60} , since the final structure has a Zr-Zr interatomic distance almost 39% larger than the isolated Zr-Zr bond length. The optimised structure of Zr_2C_{60} together with bond distances and charge density plot is shown in Figure 2.

In the relaxed configuration, the Zr atoms form shortest Zr-C bonds with carbon atoms of the (6,6) bond. The closest Zr- C_{60} bond distances are calculated to be 2.27 \AA and 2.29 \AA . This indicates that strong Zr-C bonds are formed. The C-C bond elongation is also observed in the C_{60} due to the strong interaction of Zr_2 with C_{60} . From the Bader charge analysis, it is observed that the Zr dimer has been oxidized. Each Zr atom transfers $1.34 |e|$ to C_{60} .

In the next step, we calculated the structure and reaction energy of *cis*- $\text{Zr}_2\text{N}_2\text{C}_{60}$ from Zr_2C_{60} and N_2 . The optimised structure with bond distances and cross sectional charge density plot are shown in Figure 3. The lateral interaction of N_2 on Zr_2C_{60} elongated the Zr-Zr bond distance further by 0.12 \AA compared to the Zr dimer distance in Zr_2C_{60} . Furthermore the structure of Zr_2N_2 is slightly distorted. This is reflected in the unequal charge distribution on N atoms. In the optimised structure the N-N bond distance is 1.237 \AA . The degree of activation in $\text{N}\equiv\text{N}$ is similar compared to the activation observed in *cis*- Zr_2N_2 complex unsupported by C_{60} . The reaction energy for the formation of *cis*- $\text{Zr}_2\text{N}_2\text{C}_{60}$ from N_2 and Zr_2C_{60} is calculated to be $-257.6 \text{ kJ mol}^{-1}$. The formation of *cis* complex

supported by C_{60} is facilitated further by 115 kJ mol^{-1} indicating the necessity of stabilizing the Zr dimer on C_{60} .

Finally, we calculated the structure and reaction energy of *trans*- $\text{Zr}_2\text{N}_2\text{C}_{60}$ from Zr_2C_{60} and N_2 . The optimised structure showing bond distances and Bader charges and cross sectional charge density plot are shown in Figure 4. The calculation reveals that the reaction is highly exothermic energy of -468 kJ mol^{-1} . This energy value is lower (by 28 kJ mol^{-1}) than the formation energy calculated for free Zr_2N_2 . In the presence of C_{60} the reaction energy is slightly favored. This result indicates that Zr_2 on the surface of C_{60} or a carbon nanotube would be a good choice for dinitrogen activation.

In the optimised *trans*- $\text{Zr}_2\text{N}_2\text{C}_{60}$ structure, the Zr-N bond distance is $\sim 1.96 \text{ \AA}$, which is close to the value observed in the free *trans*- Zr_2N_2 . The Zr_2N_2 unit is slightly bent and forms a butterfly type structure when it is coordinated to C_{60} . Zr-Zr and N-N separations were calculated to be 2.72 \AA and 2.50 \AA respectively and the N-N separation is slightly shorter than the N-N separation of 2.72 \AA in the free Zr_2N_2 . The Zr-Zr separation is reduced by only 0.07 \AA when the Zr_2N_2 unit is formed on C_{60} surface. The Bader charge analysis indicates that there is a greater charge transfer from Zr atoms to C_{60} and N atoms. Zr atoms have lost over all charge of $5.23 |e|$. Two N atoms gained $3.83 |e|$ and C_{60} has gained remaining $1.40 |e|$.

C. Reactions with hydrogen

The next step was to carry out additional calculations to look at the products of the reaction with H_2 to find possible routes for NH_3 formation. The first H_2 was allowed to react with *trans*- $\text{Zr}_2\text{N}_2\text{C}_{60}$ to give $\text{Zr}_2\text{N}_2\text{H}_2\text{C}_{60}$. The resulting geometry is given in Figure 5. The reaction energy for this reaction is calculated to be exothermic (energy change of $-125.44 \text{ kJ mol}^{-1}$) suggesting that the hydrogenated product is thermodynamically stable. The Zr-N and N-H bond lengths are $\sim 2.05 \text{ \AA}$ and 1.03 \AA , respectively. The Zr-Zr and N-N separations are found to be 2.52 \AA and 2.97 \AA respectively.

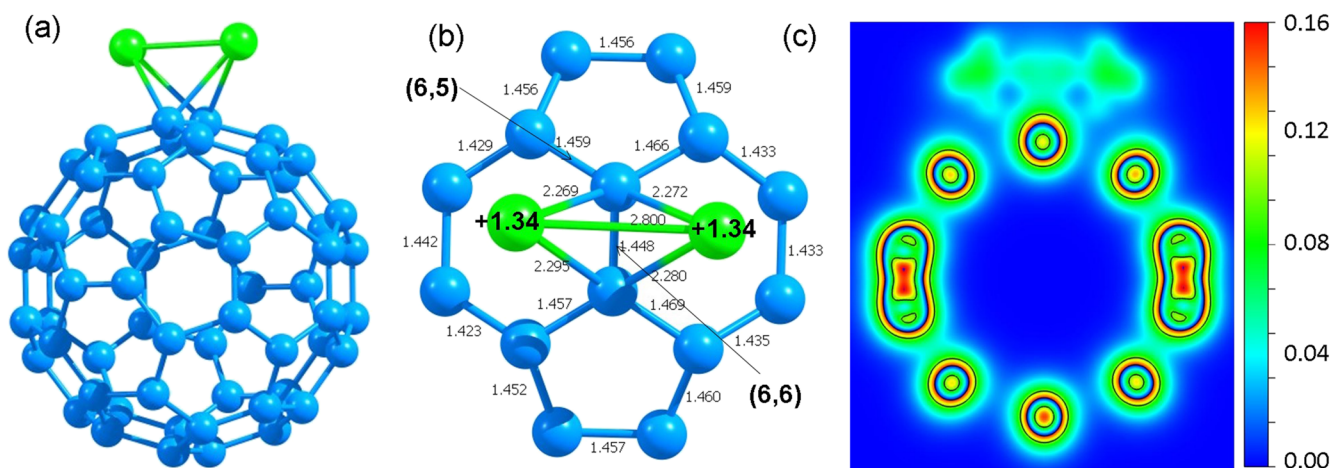

FIG. 2. (a) The optimised structure of Zr_2C_{60} (b) the expanded view structure showing bond distances and Bader charges on Zr atoms and (c) the cross sectional charge density plot showing the interaction of Zr dimer with C_{60} .

FIG. 5. (a) The optimised structure of $\text{Zr}_2\text{N}_2\text{H}_2\text{C}_{60}$, (b) the expanded view structure with bond distances and Bader charges and (c) the cross sectional charge density plot showing the interaction of $\text{Zr}_2\text{N}_2\text{H}_2$ with C_{60} .

In this reaction two moles of NH_3 and one mole of catalyst Zr_2C_{60} are yielded. This route is endothermic by as much as 409 kJ mol^{-1} and it is unlikely.

In the second route, there are two steps. In the first step, $\text{Zr}_2\text{N}_2\text{H}_4\text{C}_{60}$ reacts with one mole of H_2 to yield one mole of $\text{Zr}_2\text{C}_{60}(\text{NH}_2)\text{H}$ and one molecule of NH_3 according to the following equation.

The structure of $\text{Zr}_2(\text{NH}_2)\text{HC}_{60}$ obtained as a product in the above reaction is shown in [Figure 7](#). In the optimised structure, Zr-H, Zr-N, N-H and Zr-Zr bond distances were calculated to be 2.05 Å, 2.20/2.27 Å, 1.03 Å and 2.44 Å respectively.

In the second step, another mole of NH_3 and Zr_2C_{60} is yielded from $\text{Zr}_2(\text{NH}_2)\text{HC}_{60}$ according to the following equation:

The first step of the second route is endothermic by 123 kJ mol⁻¹ and the reaction energy for the second step is calculated to be

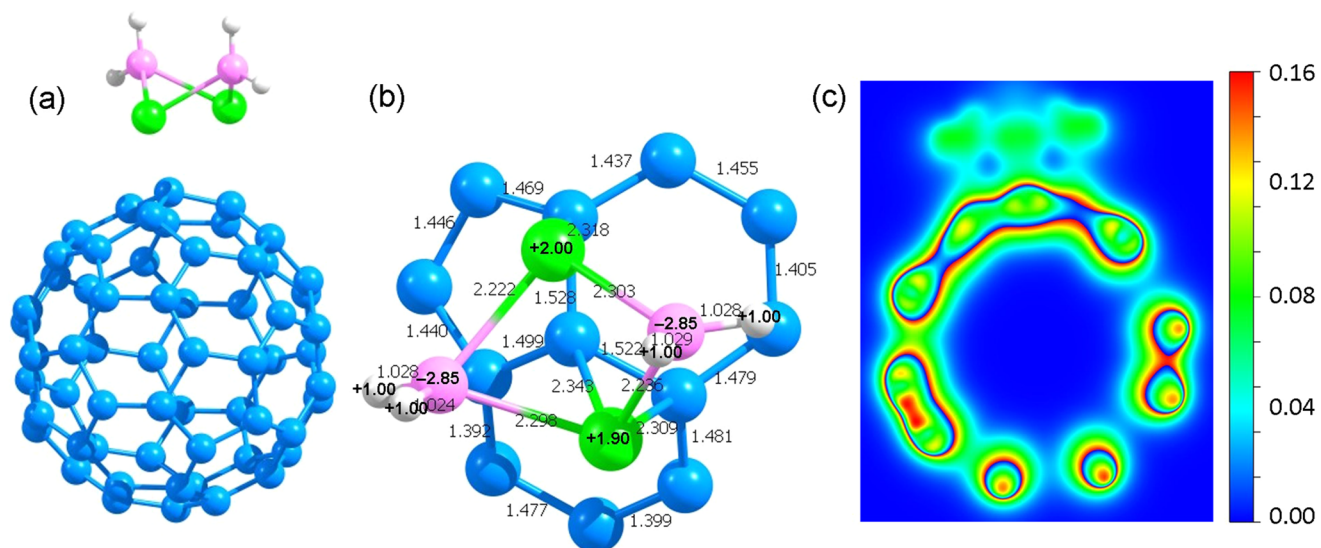

FIG. 6. (a) The optimised structure of $\text{Zr}_2\text{N}_2\text{H}_4\text{C}_{60}$ (b) the expanded view structure showing bond distances and Bader charges and (c) the cross sectional charge density plot showing the interaction of $\text{Zr}_2\text{N}_2\text{H}_4$ with C_{60} .

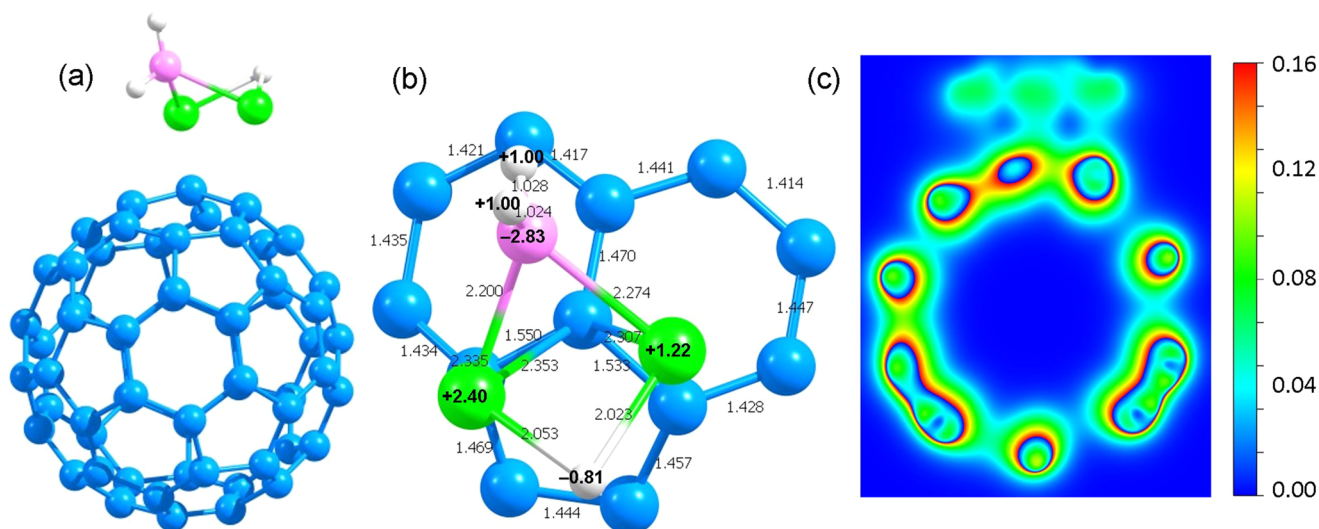

FIG. 7. (a) The optimized structure of $\text{Zr}_2(\text{NH}_2)\text{HC}_{60}$ (b) the expanded view structure together with bond distances and Bader charges and (c) the cross sectional charge density plot showing the interaction of $\text{Zr}_2(\text{NH}_2)\text{H}$ with C_{60} .

354 kJ mol^{-1} . Though this second step is unfavorable, if it were to be coupled with reaction with a further mole of N_2 , the overall process would be exothermic. Figure 8 shows a catalytic cycle consisting of all reactions and relative energy diagram for the formation of intermediates during the reaction $\text{N}_2 + 3\text{H}_2 \rightarrow 2\text{NH}_3$ catalyzed by Zr_2C_{60} .

D. Hydrogenation of *trans*- Zr_2N_2 for the formation of NH_3 (uncatalysed)

Earlier we discussed the formation of *trans*- Zr_2N_2 from Zr_2 and N_2 in the absence of C_{60} . Here we discuss the reaction energies and products during the hydrogenation with *trans*- Zr_2N_2 . The optimized structure of $\text{Zr}_2\text{N}_2\text{H}_2$ (refer to Figure 9a) is similar to

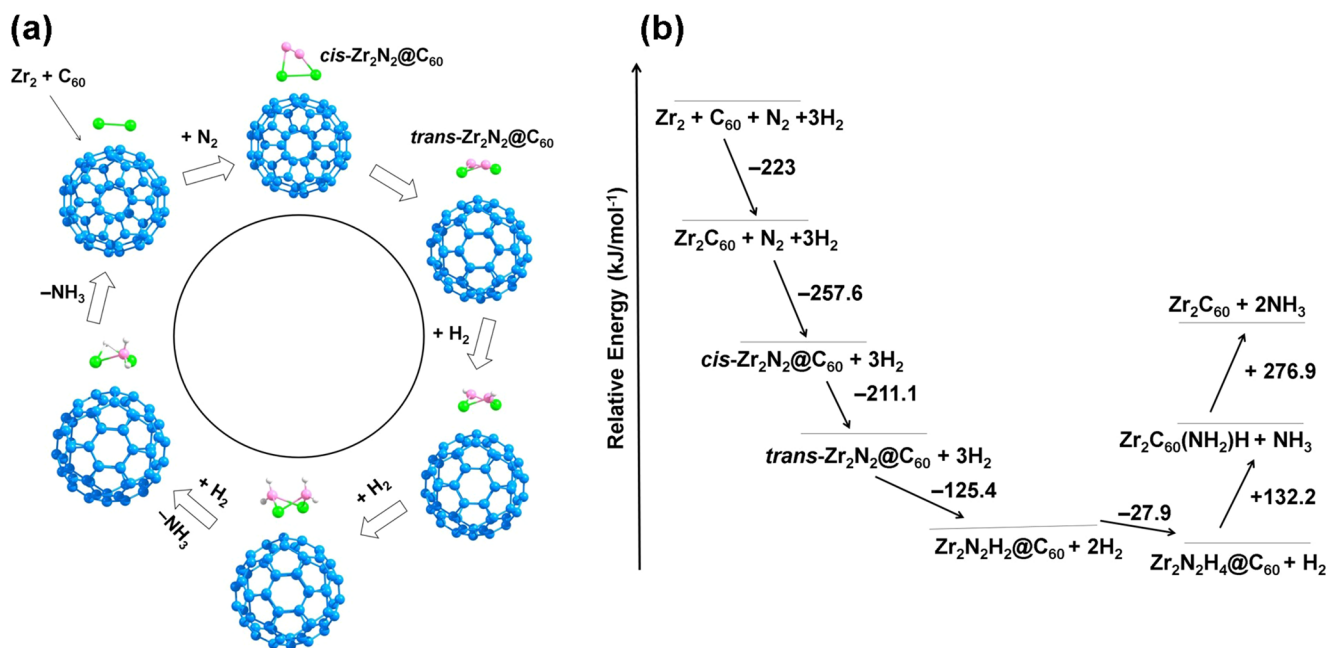

FIG. 8. (a) Catalytic cycle for the reduction of N_2 to NH_3 and (b) relative energies of intermediates formed during the reaction $\text{N}_2 + 3\text{H}_2 \rightarrow 2\text{NH}_3$ catalyzed by Zr_2C_{60} .

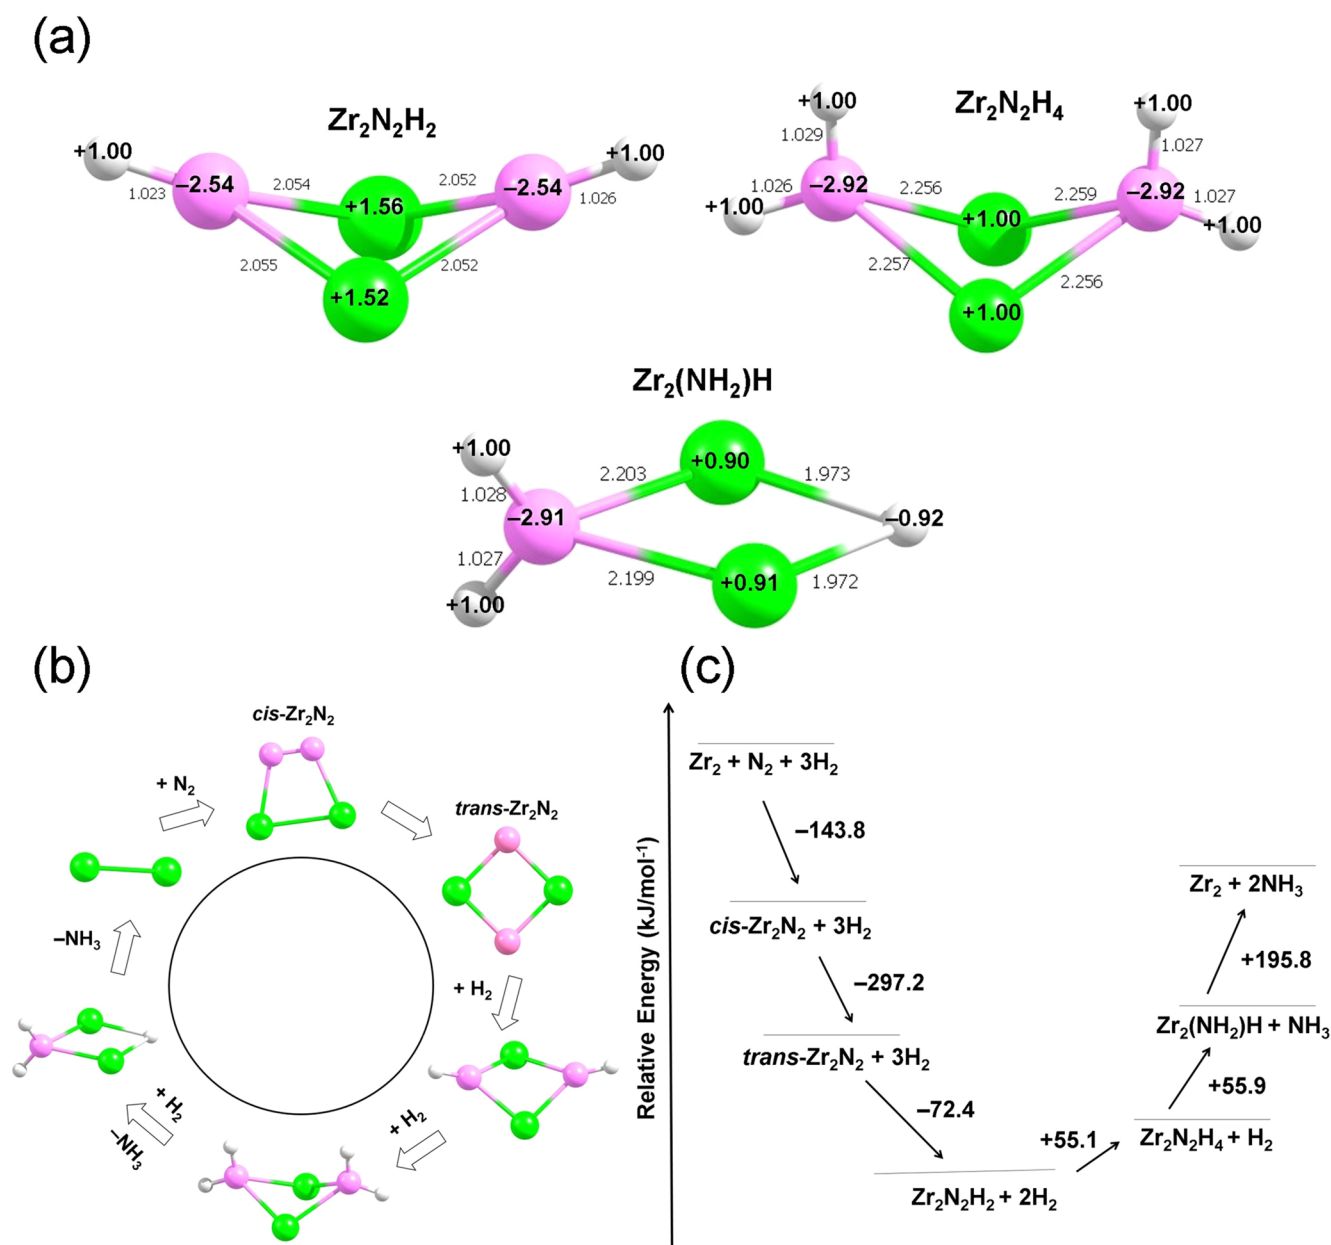

FIG. 9. (a) Optimised structures of hydrogenated products of *trans*-Zr₂N₂ together with Bader charges (b) catalytic cycle for the reduction of N₂ to NH₃ and (c) relative energies of intermediates formed during the reaction N₂+3H₂ → 2NH₃.

that of the Zr₂N₂H₂C₆₀ and exhibits a butterfly shape. There is a slight reduction in the Zr-N bond distances. There is a significant reduction in the Bader charge on Zr atoms compared to those observed in Zr₂N₂H₂C₆₀ and this can be attributed to the greater charge transfer from the Zr dimer to C₆₀. The reaction energy for the formation of Zr₂N₂H₂ from N₂ and H₂ is exothermic (−72.4 kJmol^{−1}). The addition of the first H₂ molecule with Zr₂N₂ unit supported by C₆₀ is highly exothermic (−125.4

kJmol^{−1}). This indicates that C₆₀ facilitates the addition of the first H₂ molecule.

The addition of the second H₂ molecule introduces changes in the Zr-N bonds and Bader charges on Zr and N atoms. The optimised structure almost retains its butterfly shape. The Bader charge on each N increases due to the additional charge transfer from the second H. Furthermore, the charges on Zr atom also decreases due to the absence of C₆₀. The formation energy of free Zr₂N₂H₄ is

endothermic by 55.1 kJ mol^{-1} while with C_{60} the reaction energy is $-27.9 \text{ kJ mol}^{-1}$. This clearly indicates the necessity of the stabilization of Zr dimer with C_{60} .

The energy of the first possible route for the formation of ammonia with the third H_2 ($\text{Zr}_2\text{N}_2\text{H}_4 + \text{H}_2 \rightarrow \text{Zr}_2 + 2\text{NH}_3$) was calculated. This route is endothermic by 252 kJ mol^{-1} . This reaction energy is lower by 157 kJ mol^{-1} compared to the value calculated in the presence of C_{60} .

The first step of the second route [$\text{Zr}_2\text{N}_2\text{H}_4 + \text{H}_2 \rightarrow \text{Zr}_2(\text{NH}_2)\text{H} + \text{NH}_3$] was calculated. In the first step the reaction energy is endothermic by 55.9 kJ mol^{-1} . This value is lower by 76 kJ mol^{-1} than the value calculated in the presence of C_{60} . The optimised structure of $\text{Zr}_2(\text{NH}_2)\text{H}$ is planar (refer to Figure 9a) in contrast to the structure observed with C_{60} . This is because of the asymmetric nature of $\text{Zr}_2(\text{NH}_2)\text{H}$ molecule and lower charge on Zr atoms compared to those observed in $\text{Zr}_2(\text{NH}_2)\text{H C}_{60}$. In the second step, another moiety of NH_3 and Zr_2 is yielded from Zr_2NH_3 . The reaction energy is endothermic by $195.8 \text{ kJ mol}^{-1}$. This value is $+276.9 \text{ kJ mol}^{-1}$ when this reaction is carried out in C_{60} .

IV. CONCLUSIONS

In the present study, the thermodynamic stability of Zr_2N_2 and $\text{Zr}_2\text{N}_2\text{C}_{60}$ structures and their hydrogenated configurations were calculated using density functional theory. The calculations show that the optimised *trans*- Ti_2N_2 configuration is planar but this configuration exhibits a butterfly shape when it is supported by C_{60} . Activation of dinitrogen is facilitated by the Zr dimer stabilized by C_{60} . The complete cleavage of the $\text{N}\equiv\text{N}$ bond and highly exothermic formation energy in the reaction $\text{Zr}_2\text{C}_{60} + \text{N}_2 \rightarrow \text{trans-Zr}_2\text{N}_2\text{C}_{60}$ show that C_{60} or a nanotube would be a candidate material to stabilize Zr dimer or Zr clusters to facilitate the dinitrogen activation. Consequent addition of two molecules of H_2 is exoergic in the process supported by C_{60} while only one molecule of H_2 can react exothermically with *trans*- Zr_2N_2 suggesting the necessity of stabilization with C_{60} .
